TEAM <TEAM NAME>

A judge recipe that holds on a criterion it never saw

One reply at a time · nothing criterion-specific in code · same code for both criteria

+0.081
combined, original criterion (0.754 → 0.835)

+0.035
combined, surprise criterion (0.586 → 0.621)

1.000
run-to-run consistency (46 replies)

Hold-out = cases from source replies not used as examples. 2 LLM calls per reply (max 3), temperature 0.

STEP 1 · DIAGNOSE

Where the starting judge fails

- Misses 93% of dropped conditions, in every language
- Misses 50% of certainty shifts (a hedged rule stated as a guarantee)
- Rejects 13–27% of harmless edits: reorder, filler, translation, opener
- Key insight from score.py: a catch only counts if the ORIGINAL passes

  so every false reject of a good reply costs as much as a missed edit

STEPS 2–3 · SPLIT AND IMPROVE

The recipe: code for what code can do exactly

Code (no LLM)

- Input whitelist: criterion, policy, question, ONE reply

  never the lang tag, ids, twin reply or label

- Markup inside inputs neutralised, length capped
- Number evidence: reply numbers in / not in the policy
- Per-reply call budget (max 3), enforced in code
- Signal log (JSONL) for offline re-tuning

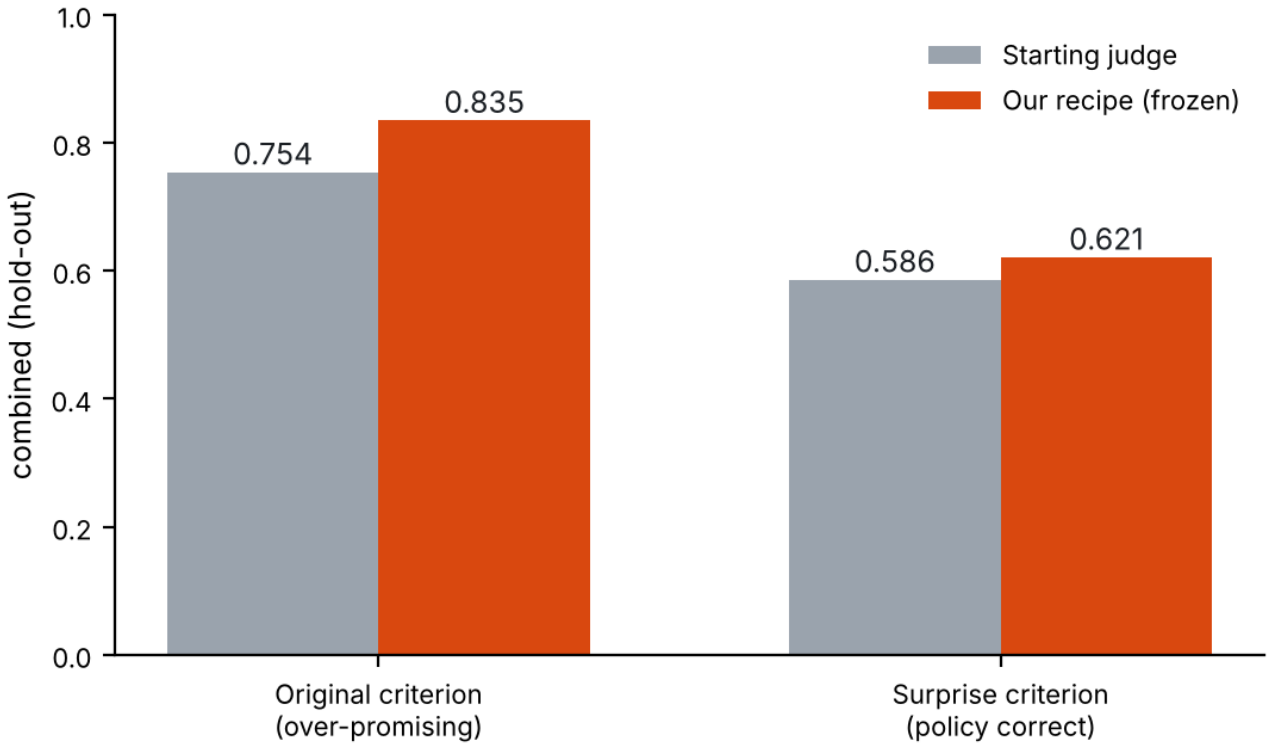

LLM strategies we measured

- C · one-word holistic verdict
- D · short check of each commitment, then VERDICT
- A · claim audit with precision guard
- Frozen: majority of C, D, A (A only if C ≠ D)
- Keep a change only if it beats C on BOTH criteria

  each view alone loses on one criterion

STEP 4 · VERIFY

Results on held-out cases

	Crit. 1	Surprise
Starting judge	0.754	0.586
Ours: majority vote	**0.835**	**0.621**
C · one-word only	0.789	0.596
D · reasoning only	0.716	0.674
A · claim audit only	0.816	0.241

Crit. 1: catch 0.656 → 0.789, kappa 0.652 → 0.746

Small hold-outs (80 / 46 replies): ±0.01 is noise

LESSONS

What did not work, and what we would do next

- Few-shot pairs made haiku over-strict: good originals failed (pass rate 0.42–0.55)
- Every single view lost on one criterion; only their vote won on both

  the audit calls omissions errors when 'errors in both directions' count
- A rule written into a prompt is a hypothesis: measure it on both criteria
- Next: exact 3-way vote (offline it reaches 0.882 / 0.642) and calibrating

  the audit's omission threshold from the example originals
