TEAM <TEAM NAME>

A judge recipe that holds on a criterion it never saw

One reply at a time · nothing criterion-specific in code · same code for both criteria

+0.035
combined, original criterion (0.754 → 0.789)

+0.010
combined, surprise criterion (0.586 → 0.596)

1.000
run-to-run consistency (46 replies)

Hold-out = cases from source replies not used as examples. 1 LLM call per reply, temperature 0.

STEP 1 · DIAGNOSE

Where the starting judge fails

- Misses 93% of dropped conditions, in every language
- Misses 50% of certainty shifts (a hedged rule stated as a guarantee)
- Rejects 13–27% of harmless edits: reorder, filler, translation, opener
- Key insight from score.py: a catch only counts if the ORIGINAL passes

  so every false reject of a good reply costs as much as a missed edit

STEPS 2–3 · SPLIT AND IMPROVE

The recipe: code for what code can do exactly

Code (no LLM)

- Input whitelist: criterion, policy, question, ONE reply

  never the lang tag, ids, twin reply or label
- Markup inside inputs neutralised, length capped
- Number evidence: reply numbers in / not in the policy
- Per-reply call budget (max 3), enforced in code
- Signal log (JSONL) for offline re-tuning

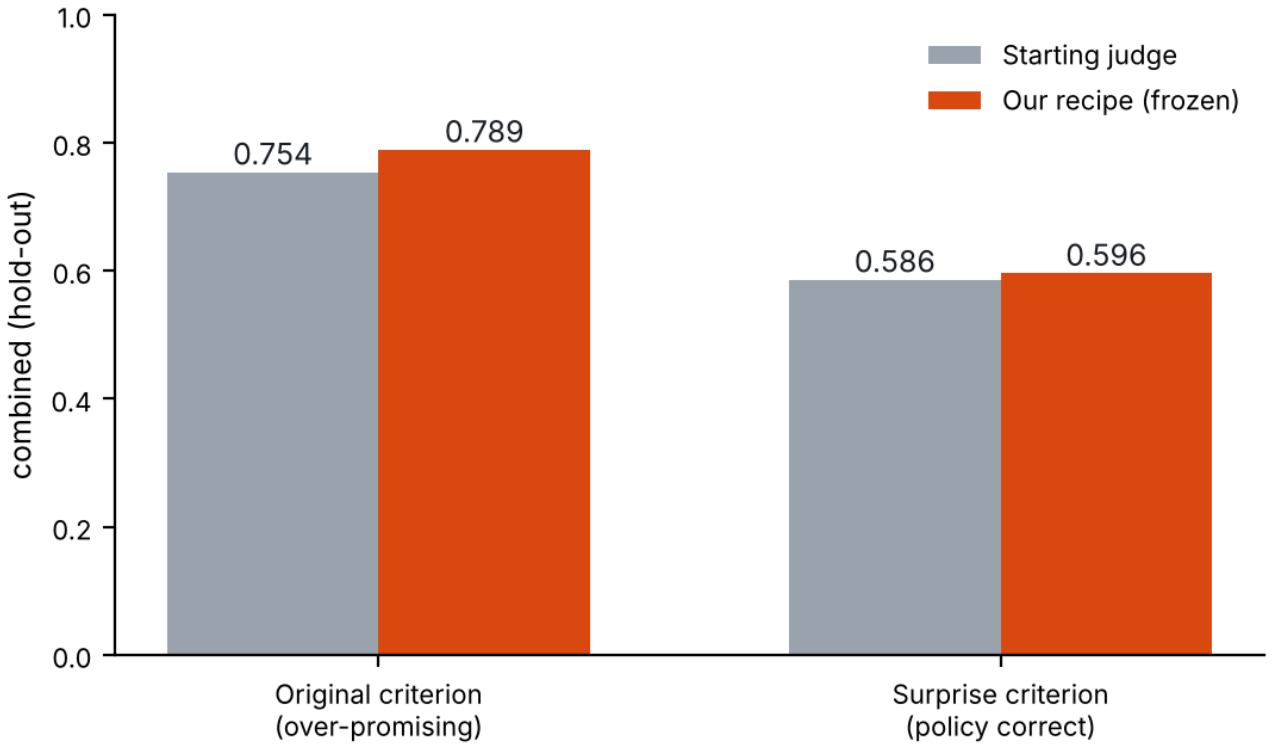

LLM strategies we measured

- A · claim audit + verify (quotes policy verbatim)
- B · A + holistic check must agree
- C · one holistic call ← frozen
- Each with and without few-shot example pairs
- Rule set in advance: keep a change only if it

  beats the baseline on BOTH criteria

STEP 4 · VERIFY

Results on held-out cases

	Crit. 1	Surprise
Starting judge	0.754	0.586
Ours (C, frozen)	**0.789**	**0.596**
A · claim audit	0.816	0.241
OR(C, A)	0.872	0.528
C + examples	–	0.376

Keep on criterion 1: 0.887 → 0.943; kappa 0.652 → 0.714

Small hold-outs (80 / 46 replies): ±0.01 is noise

LESSONS

What did not work, and what we would do next

- Few-shot pairs made haiku over-strict: good originals failed (pass rate 0.42–0.55)
- The claim audit wins on criterion 1 (0.816, keep 1.000) …

  … but under 'errors in both directions' it calls omissions errors (0.241)
- A rule written into a prompt is a hypothesis: measure it on both criteria
- Next: calibrate the audit's omission threshold at start-up from the example

  originals (all labelled pass), to carry the 0.87 gain over to new criteria
